16-2 Evolution as Genetic Change

Natural selection affects which individuals survive and reproduce and which do not. Evolution is any change over time in the relative frequencies of alleles in a population. Populations, not individual organisms, can evolve over time.

Figure 16-5 Natural selection on single-gene traits can lead to changes in allele frequencies and thus to evolution.

Organisms of one color, for example, may produce fewer offspring than organisms of other colors.

Natural selection and some of the other evolutionary forces can only act on heritable traits, namely an organism's genetic code. Because alleles are passed from parent to offspring, those that confer beneficial traits or behaviors may be selected, while deleterious alleles may not. Acquired traits, for the most part, are not heritable.

POPULATIONS

A dynamical theory for the evolution of the genetic code is presented, which accounts for its universality and optimality. The central concept is that a variety of collective, but non-Darwinian, mechanisms likely to be present in early communal life generically lead to refinement and selection of innovation-sharing protocols, such as the genetic code.

Collective evolution and the genetic code | PNAS

Studying these responses, Andrews et al. developed a hypothetical framework describing how genetic drift conceptual development might progress: They suggest students may shift from (1) naive and limited conceptions of evolution and genetics to (2) a state where students are aware of various evolutionary processes (e.g., genetic drift) but still ...
