Climate And Sea Level Change

Global warming is causing global mean sea level to rise in two ways. First, glaciers and ice sheets worldwide are melting and adding water to the ocean. Second, the volume of the ocean is expanding as the water warms.

Climate Change: Global Sea Level | NOAA Climate.gov

After a period of approximately 2,000 years of little change (not shown here), global average sea level rose throughout the 20 th century, and the rate of change has accelerated in recent years. 1 When averaged over all of the world's oceans, absolute sea level has risen at an average rate of 0.06 inches per year from 1880 to 2013 (see Figure 1). Since 1993, however, average sea level has risen at a rate of 0.11 to 0.14 inches per year—roughly twice as fast as the long-term trend.

Climate Change Indicators: Sea Level | Climate Change ...

Sea level can rise by two different mechanisms with respect to climate change. First, as the oceans warm due to an increasing global temperature, seawater expands—taking up more space in the ocean basin and causing a rise in water level. The second mechanism is the melting of ice over land, which then adds water to the ocean.

Potential Sea-Level Changes If Earth's climate continues to warm, then the volume of present-day ice sheets will decrease. Melting of the current Greenland ice sheet would result in a sea-level rise of about 6.5 meters; melting of the West Antarctic ice sheet would result in a sea-level rise of about 8 meters.

Unfortunately, the ocean can only absorb so much. And according to a new study, sea-level rise is one many threats that climate change poses to birds across 90% of the United States. As sea levels rise, coastal birds have lost safe, healthy coastal areas to nest.

Climate Change Threatens Seabirds on Both Land and Sea ...

Sea level rise is caused primarily by two factors related to global warming: the added water from melting ice sheets and glaciers and the expansion of seawater as it warms. The first graph tracks the change in sea level since 1993 as observed by satellites.

Changes in sea level relative to the land vary by region. Along the U.S. coastline, sea level has risen the most along the Mid-Atlantic coast and parts of the Gulf coast, where some stations registered increases of more than 8 inches between 1960 and 2015. Sea level has decreased relative to the land in parts of Alaska and the Pacific Northwest.

According to Wuebbles, multiple lines of evidence support the existence of climate change: Land and sea surface temperatures are increasing, lower atmosphere temperature is increasing, the heat content of the ocean is increasing, the average humidity of the atmosphere is increasing, and the extent of Arctic sea ice is shrinking, as is the mass of the Earth's glaciers.
