A proton exchange membrane fuel cell transforms the chemical energy liberated during the electrochemical reaction of hydrogen and oxygen to electrical energy, as opposed to the direct combustion of hydrogen and oxygen gases to produce thermal energy.. A stream of hydrogen is delivered to the anode side of the MEA. At the anode side it is catalytically split into protons and electrons.

The proton exchange membrane (PEM) fuel cell consists of a cathode, an anode and an electrolyte membrane. Hydrogen is oxidized at the anode and the oxygen is reduced at the cathode. Protons are transported from the anode to the cathode through the electrolyte membrane and the electrons are carried over an external circuit load.
